

## OPERATION

Certain hardware components require manual operation:

### **Safety catch, blowback restrictor and washing position**

Under the sash the hinge has an automatically safety catch. This is operated by slightly closing the sash after it has opened out against the restrictor and then lifting the restrictor catch up to release the sash for further opening.

The safety catch then stops in amore open position, where it locks the sash and prevent it from blowing back and forth. This device is operated the same way as explained above, both for the further opening and for closing.

In addition the safety catch functions as a washing position lock when the frame is completely turned around.
